TCP Server Tomcat is a small and compact piece of software that helps you analyze the TCP connections. This is a free tool and you do not need to pay a cent to use it. It is a stand-alone and portable application that runs on Windows, Linux and Mac OS X systems. The software provides real-time data on how your application performs on different TCP protocols. It is a freeware that lets you analyze the data sent and received over any TCP listener. With the help of TCP Server Tomcat, you can analyze the different TCP protocols, test the capacity of your TCP listener and see whether it has any flaws. TCP Server Tomcat has no restrictions and does not require installation. However, since it is a portable utility, you can run it using a USB flash drive. It has an intuitive and user-friendly interface that is easy to use. TCP Server Tomcat includes four main panels, one for each of the TCP listeners you can use to test the TCP clients. You will be happy to learn that the utility automatically reads the IP address of the client based on the NIC source you select. The app also provides you with information about the status, result, bytes received and errors detected. Among the features of TCP Server Tomcat, you will find an option to test any TCP listener. Additionally, you can select which TCP protocol you wish to test. The tool has an option that is used to view the output of the test results. You can view the bandwidth or transfer information to help you test the capacity of the listener. Another feature is the option to test the transfer speed in Mbps or KBps. You can run multiple TCP sessions from the same IP address and multiple servers and test them. You can choose to save all the datagrams in a single file or separate files. You can also configure the output using the Log Format option. Since the utility generates TCP packets, you can choose to view the original transferred data. You can also choose to view the data as it was transferred to the computer or the data that was sent to another destination server. TCP Server Tomcat is a lightweight piece of software that is designed to help you analyze the TCP sockets to determine whether they are working optimally based on the logs generated. It seems to be that as of "bommerang" (2005-05-06), the current (Sept. 2010) version of the Linux kernel (Linux 2.6.37) is not compatible with the server socket used in the NetBSD kernel (sockets were changed in v3.1). It is possible to compile the kernel with both the new and the old server socket. NetBSD 5.0 rc3 (1998-05-28) includes the new server socket. (Note: A bug in the NetBSD kernel used by the Linux kernel is preventing successful compilation with the server socket from v3.1. This bug is fixed in NetBSD 5.0 rc4 which will ship in two weeks). If the server socket is enabled, and if NetBSD is compiled with the server socket, then an old server socket will be used. If the server socket is not enabled, then NetBSD will use the new server socket. Note that the client and server socket in the Linux kernel are different (the client socket supports TCP only, whereas the server socket supports both TCP and UDP). In a previous version of this patchset, the Linux kernel was compiled with the old client and server sockets, but the NetBSD kernel was not, so the NetBSD code could not be successfully compiled (because the server socket was not available in the Linux kernel). Until v3.1, the NetBSD and Linux kernels shared a number of code modules. One of these modules was the server socket. With v3.1, this code has been split into a new module which is used for NetBSD and an old module which is used for Linux. In the previous version of this patchset, the NetBSD and Linux kernels shared the old server socket code, so if the server socket was enabled, then the NetBSD kernel could not be successfully compiled. For a kernel that is compiled with the server socket, the server socket (in NetBSD) will be used. If the server socket is disabled, the NetBSD kernel will use the new server socket. If the NetBSD kernel is compiled with the server socket, and the Linux kernel is not compiled with the server socket, then the NetBSD code will not compile. The NetBSD kernel will use the new server socket if the
